

Interacting Mindreaders

Stephen A. Butterfill

December 28, 2011

Abstract

What evidence grounds ascriptions of thoughts and actions, and how does the evidence support the ascriptions? In answering this question, philosophers sometimes focus on mere observation, ignoring interaction. The only evidence considered is evidence that would be available to mindreaders observing their targets but in no position to interact with them. The present paper, which focuses on goal ascription, argues that this is a mistake and identifies evidence available only to mindreaders capable of interacting with their targets. Being poised to interact with others may make it possible to know things about their thoughts and actions which one might not otherwise be in a position to know. This has consequences for the possible roles of interaction in explaining the evolution and development of mindreading.

1. Mindreading: the normative project

Mindreading is the process of identifying thoughts and actions on the basis of bodily movements, somewhat as reading is the process of identifying propositions on the basis of inscriptions (Apperly 2010, p. 4). Contrast a mindreader who is, or appears to be, capable of interacting with her targets and a mindreader who can manifestly only observe. Is it possible that the interacting

mindreader is in a position to know things which she would be unable to know if she were unable to interact with her targets? Our aim in this paper is to argue that the answer is a qualified 'yes'.

The question is about the evidential basis of mindreading, not about what sorts of mechanisms are involved. While philosophers have engaged with questions about mechanisms (such as whether mindreading involves a process of simulation or of theorizing or some combination of the two), comparatively little effort has recently been devoted to issues about what evidence could ground mindreading.

Our question is part of a broader question, What is the evidential basis for ascriptions of thought and action and how does the evidence support the ascriptions? The most sustained attempts to answer this question, Davidson's (1984; 1990), Lewis' (1974) and Dennett's (1987), do not exploit the possibility of interaction. The evidence and principles they consider are available to manifestly passive observers. So on their theories, a purely passive mindreader observing from behind a one-way mirror is on a par with a mindreader who, actually or apparently, could interact with those she seeks to interpret. The two are on a par in this sense: in principle the same evidence could be available to each, and each can exploit the same principles in moving from evidence to ascriptions of thought. Of course none of these theories is incompatible with the idea that interaction might be useful for mindreading in practice. The point is just that, on these theories, interaction makes no difference to the theory. In this paper we aim to show that mindreaders actually or apparently capable of interacting with their targets are at an advantage not only in practice but also in theory. Their ascriptions could rely on evidence and principles which would be unavailable if they were entirely passive observers.

Why investigate this claim? One reason is simply because the investigation will enable us to revise and extend existing accounts of the evidential basis of mindreading in ways that make them more accurate and comprehensive. Another motive con-

cerns the emergence, in evolution and in development, of mindreading. Several researchers have offered quite general conjectures about how interaction might explain the emergence of sophisticated forms of cognition. One view is that needs to interact with others have driven and shaped some aspects of cognition.¹ We shall not speak to this view here. Another view is that abilities to interact with others may have fostered the emergence in evolution—or, on a related view, in development—of sophisticated forms of cognition including social cognition and, in particular, mindreading.² Studying how interaction broadens the evidential basis of mindreading will eventually point to one way of filling in some details on just how interaction might facilitate the emergence of mindreading.

Our claim needs to be qualified in several ways. First, we should highlight something already explicit that has not yet been emphasised: the claim applies not just to mindreaders who actually could interact with their targets but also to mindreaders who appear to their targets to be potential interaction partners (even if they are not). Trading the risk of a minor misunderstanding for concision we use the term ‘interacting mindreader’ to refer to both groups; similarly, references to mindreaders who ‘only observe’ must be understood as excluding those who appear to their targets to be interaction partners. Only cases involving the first group—mindreaders who actually could interact—are likely to be of wider interest. Cases involving misleading appearances might be regarded as artefacts of the model. Any application of our claim to understanding evolution or development is bound to focus on cases where mindreaders actually could interact with their targets.

A second qualification concerns the scope of mindreading.

¹ E.g. Knoblich & Sebanz (2006, p. 103) suggest that ‘functions traditionally considered hallmarks of individual cognition originated through the need to interact with others’ and that ‘perception, action, and cognition are grounded in social interaction.’

² Moll & Tomasello (2007, p. 1) argue for the ‘Vygotskian Intelligence Hypothesis’ according to which ‘the unique aspects of human cognition ... were driven by, or even constituted by, social co-operation.’ See also Hughes & Leekam (2004), Hughes, Fujisawa, Ensor, Lecce & Marfleet (2006), Tomasello & Carpenter (2007) and Tomasello (2008).

In most discussions of mindreading, the focus is on ascription of beliefs and other mental states to individuals. But in what follows we shall focus on the ascription of goals to actions. Some might claim that goal ascription is not mindreading, perhaps because identifying relations between actions and the outcomes to which they are directed does not necessarily involve ascribing mental states. Our view is consistent with this claim (and with its negation). Evidence for ascriptions of belief and of other mental states often includes the occurrence (and non-occurrence) of goal-directed actions. Identifying these actions typically requires goal ascription. In some cases, then, evidence for the ascription of a goal will indirectly support the ascription of a belief or other mental state—the evidence will support the ascription of a goal to an action, and this ascription will in turn support the ascription of a belief (say) to the agent of the action. Accordingly, even those who deny that goal ascription is mindreading should agree that sometimes evidence for a goal ascription is indirectly evidence for the ascription of a belief or other mental state. So whether or not goal ascription is deemed to be mindreading, a mindreader's access to evidence for mindreading depends in part on her access to evidence for goal ascription. Our plan is to show that interacting mindreaders could make use, in ascribing goals, of evidence and principles which are not available to mere observers (who do not even appear to be in a position to interact with their targets). In doing this we will be showing that mindreaders who are (or appear) poised to interact with others could know things about their minds which they might not otherwise be in a position to know.

2. Goal ascription

Purposive action is action directed to the realisation of one or more outcomes. Goal ascription is the process of identifying to which outcomes others' purposive actions are directed. To illustrate, suppose that Hannah kicks a ball thereby both preventing her sisters from scoring and also breaking a window.

Asked about episode, Hannah might protest that the goal of her action was not to break the window but only to reverse the others' advance. As this illustrates, among the actual and possible outcomes of an action, only some are outcomes to which the action was directed. Goal ascription is the process of identifying from among an action's actual and possible outcomes those to which it is directed.

We focus on goal ascription partly because this simplifies our argument, but mainly because goal ascription is widely thought to be among the very earliest components of mindreading to emerge (or, if goal ascription is not mindreading, then it is a late precursor).³ By showing that interacting mindreaders may have access to evidence for goal ascriptions which is unavailable to those who merely observe, we may be able to indicate ways in which interaction could facilitate the emergence, in evolution or development, of more sophisticated forms of mindreading.⁴

Because goal ascription has received little attention, in this section we shall briefly review some potential benefits of being able to identify goals and then consider what sort of evidence might support goal ascription.

It is a familiar idea that goal ascription enables one to learn from others' successes. For example, if you know or can guess that another agent's actions are directed to opening a nut, you may then be in a position to infer that the unfamiliar pattern of actions she is performing constitute a means to open nuts. In a different case, knowing the goal of another agent's actions may enable you to discover a new use for a tool. A slightly less familiar idea is that goal ascription enables one to learn from others' failures as well as their successes. For example, suppose that while you are searching for some peanuts another agent

³ See, for example, Gergely, Nadasky, Csibra & Biro (1995) and Woodward (1998). See also Baillargeon, Scott & He (2010, p. 111, Box 1) on two subsystems and Povinelli (2001) on 'behavioural regularities' whose specification sometimes appears to involve goal-directed action.

⁴ There are various ways of understanding the idea that mindreading may come in several forms, some less conceptually or cognitively demanding than others. For a range of views, see Apperly & Butterfill (2009), Call & Tomasello (2005), Doherty (2006), O'Neill (2005) and Wellman & Phillips (2001).

attempts but fails to reach for a closed container. In some circumstances, if you know that the goal of the agent's action was to obtain the peanuts then you now have evidence as to where they might be.⁵ This is one illustration of how goal ascription could in principle enable us to learn from others' failures (Want & Harris 2001 offer another).

Goal ascription enables one to predict and manipulate others' actions. If you know that an agent is engaged in a sequence of actions whose eventual goal involves retrieving some object, you may be able to predict that the agent will go to where the object is at some point.⁶ Equally, in some cases knowing this much about the goal of another's actions may enable you to assist them, either by retrieving the object for them or else by revealing the object's location to them.⁷

Goal ascription is also instrumental for ascribing propositional attitudes. We have already mentioned that such ascriptions often involve confirming predictions about actions which in turn typically involves identifying the goals of those actions (on page 4). In addition, knowing which outcomes an action is directed to may constrain hypotheses about what an agent intends as well as potentially providing information concerning what the agent knows, believes or desires. For example, if we know that the goal of an agent's action is to retrieve some peanuts, and if we also know where all the peanuts are, we may be able to infer that she does not know where the peanuts are, or that she falsely believes that some of the peanuts are over there.⁸ (Of course this can also work the other way: information about an agent's beliefs or other mental states may support conclusions about her goals. Belief- and goal-ascriptions are mutually constraining.)

⁵ Hare & Tomasello (2004) exploit this principle in testing chimpanzees' abilities to ascribe goals.

⁶ For an application see Hare, Call & Tomasello (2001).

⁷ For a paradigm involving the former see Warneken, Hare, Melis, Hanus & Tomasello (2007); on the latter, see Liszkowski, Carpenter & Tomasello (2008).

⁸ Wimmer & Mayringer (1998) exploit this possibility in testing children's abilities to ascribe false beliefs.

Now that we have reviewed some of the benefits goal ascription can bring, what evidence could support ascriptions of goals to actions? Consider the claim that knowledgeably identifying the goals to which actions are directed depends on knowledge of the agents' intentions which in turn depends on knowledge of their beliefs, desires and other mental states. If this claim were true, there would be no such thing as a theory of the evidential basis of goal ascription, only a theory of the evidential basis of mindreading more generally.

The falsity of this claim seems to be assumed in both developmental and comparative research on goal ascription.⁹ We know of no compelling reason for taking this claim to be true. After all, it is consistent with rejecting the claim to recognize that ascriptions of goals to actions constrain, and are constrained by, ascriptions of intentions and other mental states. The existence of such constraints does not show that one could not know something about the goals of actions while knowing nothing about the agents' mental states. Further, there do seem to be situations where knowledge of agents' goals does not require any knowledge of their mental states. For instance, suppose that two people are sitting opposite each other at a low table which is sparsely populated with objects. The objects are all out in the open; manifestly, both can clearly see them. If one person reaches to grasp one of these objects (the duck, say), must the other ascribe beliefs or other mental states in order to knowledgeably identify the goal of her action as that of grasping the duck? On the face of it, she need not. Even if she had no ability to ascribe mental states, it seems she might nevertheless be in a position to identify the goal of the other's action.

While not decisive, these considerations are perhaps sufficient to motivate exploring what evidence might ground goal ascription. According to what Csibra and Gergely call 'the principle of rational action':

'an action can be explained by a goal state if, and

⁹ Compare Gergely et al. (1995), Woodward (1998) and Penn & Povinelli (2007) among many others.

only if, it is seen as the most justifiable action towards that goal state that is available within the constraints of reality.’¹⁰

Taking this idea as a rough starting point, we propose that these facts:

1. action a is directed to some goal;
2. actions of a ’s type are normally capable of being means of realising outcomes of G ’s type in situations with the salient (to any concerned) features of this situation;
3. no alternative type of action is both typically available to agents of this type and also such that actions of this type would be normally be significantly better¹¹ means of realising outcome G in situations with the salient features of this situation;
4. the occurrence of outcome G is typically desirable for agents of this type;

and

5. there is no other outcome, G' , the occurrence of which would be at least comparably desirable for agents of this type and where (2) and (3) both hold of G' and a

may jointly constitute defeasible evidence for the conclusion that:

6. G is a goal to which action a is directed.

¹⁰ Csibra & Gergely (1998, p. 255); cf. Csibra, Bíró, Koós & Gergely (2003). A related but different ‘principle of efficiency’ has been formulated by Southgate, Johnson & Csibra (2008, p. 1061): ‘goal attribution requires that agents expend the least possible amount of energy within their motor constraints to achieve a certain end.’

¹¹ An action of type a' is a better means of realising outcome G in a given situation than an action of type a if, for instance, actions of type a' normally involve less effort than actions of type a in situations with the salient features of this situation and everything else is equal; or if, for example, actions of type a' are normally more likely to realise outcome G than actions of type a in situations with the salient features of this situation and everything else is equal.

We suggest that the above inference, from (1)-(5) to (6), is a route to knowledge of the goals of actions in this sense: it would be possible to know the premises without already knowing the conclusion; and, in some cases knowing the premises could put one in a position to know the conclusion.¹²

Why accept this? Suppose that (1)-(5) are facts and that G is not a goal to which action a is directed. Then from (1) we know that a has a goal, call it G' . And from (5) we can infer that either (i) the action, a , was not of a type that is normally capable of being a means to the outcome to which it was directed, or (ii) a significantly better (for instance, a more reliable or less effortful) means of achieving G' is typically available to agents of this type, or (iii) G'' 's occurrence would be significantly less desirable than G 's occurrence for agents of this type. So the agent's action fell short of being appropriate or optimal in some way, or the agent has atypical preferences or capabilities, or the situation is not normal. While any of these is possible—and perhaps in some cases even to be expected—there are also circumstances in which it is reasonable to suppose that none obtains, that the situation will be normal in relevant respects, that agents will have typical preferences and capabilities and that they will act in ways that are appropriate and (in the limited sense in play here) optimal. In such circumstances, the above inference can serve as a route to knowledge of the goals of actions. The existence of this route to knowledge shows that goal ascription doesn't invariably depend on mental state ascription.

Note that we are not suggesting that the above inference captures the only route to knowledge of the goals of actions, or that it provides anything like a comprehensive theory of the evidential basis of goal ascription. This route to knowledge has only limited applications. For example, it cannot be used when

¹² Knowledge of the premises may not require explicit knowledge of what others find obvious, what is salient to them or what makes actions better for them. It is arguably sufficient that the individual ascribing a goal is entitled to rely on being sufficiently similar to the target of her ascription with respect to what she finds obvious, what makes one action a better or worse means of realising an outcome than another action for her, what is desirable to her, and what is salient to her.

an action is the best available means of achieving two or more comparably desirable outcomes. The point of this brief discussion was only to consider the sort of evidence that can bear on goal ascription and to show that even those incapable of ascribing mental states like belief might nevertheless have evidence sufficient for goal ascription.

Our narrow aim in what follows is to show that some routes to knowledge of the goals of actions are available only to interacting mindreaders and not to those who merely observe. Having in this section introduced goal ascription as a topic, the next step is to identify an obstacle to acquiring knowledge of the goals of actions, one which we will eventually show can be avoided where mindreaders can (or appear to be able to) interact with their targets.

3. The problem of opaque means

While we lack a detailed theory of the evidential basis of goal ascription, it is certain that the evidence for goal ascription sometimes includes considerations about which ends actions are means to. Suppose an observer faces an action but cannot identify ends to which it could be a means. This may prevent her from recognizing the action's goal¹³ by depriving her of evidence. To illustrate, contrast two cases of tool use. In one case, someone uses a reamer to juice a lime; in the other, someone else scores shag with a lame to prevent a loaf from cracking. Without communication, repetition or convention, an observer familiar with reamers but not lames may be able to identify the goal of the first action only. As this illustrates, ignorance about to which ends actions are means can be an obstacle to goal ascription. Call this the problem of opaque means.

We are not suggesting that no observer could ever identify the goal of any action she fails to recognise as a means to achiev-

¹³ It is possible that some actions have more than one goal. To reduce parenthetical qualifications we shall write as if actions had only one goal. All of our key claims and arguments are consistent with the possibility of actions with more than one goal.

ing that goal, of course. Of course opaque means are not in every case an insurmountable obstacle to goal ascription. This point is neither novel nor surprising: opaque means sometimes deprive interpreters of evidence and so prevent goal ascription.

Some of the most plausibly unique aspects of human cognition depend on our abilities to recognise the goals of novel behaviours involving tools, and of communicative gestures. If goal ascription is based on entirely observation (so that the possibility of interaction is ignored), the problem of opaque means is likely to arise in both cases. We have just seen an illustration of how the problem of opaque means arises where tools are used to unfamiliar ends. Relatedly, it is also likely to arise where actions involve multiple steps that do not form a familiar sequence, can occur in various orders and can be interspersed among other activities; as in preparing spirit from grain, for example.

The problem of opaque means also affects communicative actions because these characteristically have goals which the actions are means to realising only because others recognise them as means to realising those goals (a Gricean circle). To illustrate, consider an experiment from Hare & Tomasello (2004, experiment 3) whose two main conditions are depicted in figure 1 on the next page. The pictures in the figure stand for what participants, who were chimpanzees, saw. The question was whether participants would be able to work out which of two containers concealed a reward. In the condition depicted in the left panel, participants saw a chimpanzee trying but failing to reach for the correct container. Participants had no problem getting the reward in this case, suggesting that they understood the goal of the failed reach. In the condition depicted in the right panel, a human pointed at the correct container. Participants did not reliably get the reward in this case, suggesting that they failed to understand the goal of the pointing action.¹⁴ This may be be-

¹⁴ The contrast between the two conditions is not due merely to the fact that one involves a human and the other a chimpanzee. Participants were also successful when the failed reach was executed by a human rather than another chimpanzee (Hare & Tomasello 2004, experiment 1).

Figure 1: A failed reach (left) and a helpful point (right). Reproduced from Hare & Tomasello (2004, p. 557, figure 4).

cause of the problem of opaque means. One theoretically possible explanation of these findings is that the participants could identify to which end a failed reach might be a means, but not to which end a communicative gesture might be a means.¹⁵ Whatever the truth about the chimpanzees' performance, this possibility illustrates how the problem of opaque means can be an obstacle to exploiting communicative gestures.

This, then, is the problem of opaque means: failures to identify to which ends actions are means can impair goal ascription. The problem is potentially a problem for interpreters given the standard, purely observational models of interpretation. It is not our intention to suggest that the problem of opaque means is a problem *for models of interpretation*. Rather, it is a potential problem *for interpreters*.

That the problem of opaque means exists is the first premise in our argument that models of interpretation based on pure observation are less powerful than models taking into account the possibility of interaction. They are less powerful in this sense: some routes to knowledge of the goals of actions are available only where a model of interpretation takes the possibility of interaction into account. In what follows we shall suggest that

¹⁵ Hare and Tomasello consider several explanations for their findings including 'the hypothesis that chimpanzees do not understand the communicative intent of a cooperative-communicative experimenter' (2004, p. 580). Moll & Tomasello (2007, pp. 5–7) argue for a hypothesis along these lines by appeal to a range of related findings.

abilities to engage in joint action with others provides a route to knowledge of the goals of other agents' actions which avoids the problem of opaque means. This is one way in which moving away from a purely observational model of interpretation yields a richer evidential base for ascriptions.

4. Joint action

Our overall aim is to defend this claim: there are routes to knowledge of the goals of others' actions which are closed to interpreters who merely observe their targets but open to interpreters capable of interacting with their targets. As a preliminary to defending this claim, we need to specify the types of interaction which are relevant. We shall focus on joint action.

***Much disagreement about what it is. Necessary condition is distributive goal. If people want to disagree, this is only terminological.

5. Your-goal-is-my-goal: a route to knowledge

If an interpreter is able to interact with her targets, if she is not limited to merely observing them, how might this provide her with a route to knowledge of the goals of their actions? The intuitive idea we started with hinges on joint action, a particular form of interaction in which the actions of two or more agents are directed to a single goal (see section 4). Our intuitive idea was this: if an interpreter is engaged in joint action with her target, it's easy for the interpreter to know what the goal of her target's actions is because this goal is the goal of her own actions. So if she knows the goal of her own actions and she knows that she is engaged in joint action with her target, then she already knows what the goal of her target's actions are.

Of course this intuitive idea won't work as it stands. For the inference it captures relies on the premise that the interpreter

and her target are engaged in joint action. But for the interpreter to know this premise—for her to know that they are engaged in joint action—it seems she must already know which goal her target’s actions are directed to. Worse, on many accounts of joint action the mere truth of the premise would require the interpreter to know the goal of her target’s actions.¹⁶ Apparently, then, engaging in joint action presupposes, and therefore cannot be a source of, knowledge of others’ goals.

Fortunately there is a way around this. For there are various cues which signal that one agent is prepared to engage in joint action with another. Seeing a stranger with the haggard look of a new parent struggling to get his twin pram on to the bus, you grab the front wheels and make eye contact, raising your eyebrows and smiling. (The noise of the street rules out talking, and you can barely speak the local language anyway.) In this way you signal that you are about to act jointly with the stranger, to lift the pram with him. Since the stranger is fully committed to getting his pram onto the bus, he knows what the goals of his own actions will be. This enables him to infer the goal of your imminent actions: your goal is his goal, to get the pram onto the bus.

Our suggestion, then, is that the following inference characterises a route to knowledge of others’ goals:

1. You are willing to engage in some joint action¹⁷ or other with me
2. I am not about to change which goal my actions will be directed to.

Therefore:

3. A goal of your actions will be my goal, the goal I now envisage that my actions will be directed to.

¹⁶ *ref

¹⁷ *What notion of joint action is needed here? Any will do as long as it involves distributive goals.

Call this the *your-goal-is-my-goal inference*. To say that this inference characterises a route to knowledge implies two things. First, in some cases it is possible to know the premises, 1–2, without already knowing the conclusion, 3. Second, in some of those cases knowing the premises would put one in a position to know the conclusion. We shall consider these points in turn

Is it ever possible to know the premises without first knowing the conclusion? Consider the first premise. Sometimes in the right contexts an individual can recognize in another's facial expressions, engaging gestures or synchronized bodily movements that she are about to engage in joint action with him. Exploiting these indicators does not typically depend on knowing the particular contents of any of their beliefs, desires or goals. Expressions, gestures and movements can naturally indicate imminent jointness in much the way they can also naturally indicate emotions.¹⁸ Of course these indicators provide no guarantee that others are genuinely willing to engage in joint action. But they are sufficiently reliable to ground knowledge in some cases. The existence of such indicators shows that knowing the first premise of the above inference does not require already knowing which particular goals the other has.

Not everything needs to rest on indicators, however. It is sometimes possible to know that others are about to willing in joint action with you even without relying on such indicators. Thanks to widespread dispositions to act jointly, in some situations it is reasonable to take for granted that others are willing to act jointly. For example, this is often so for children surrounded by family or familiar adults who are struggling with a coat. And in at least some subcultures people using public transport can reasonably take for granted that, within limits, those around them will act jointly with them when the need is clear. Of course dispositions to engage in joint action may vary between cultural groups and situations. This may be fatal for the peripatetic cosmopolitan, but for others what matters is not

¹⁸ Ideas along these lines are suggested by the discussion of *emergent coordination* in Knoblich, Butterfill & Sebanz (2010).

whether the dispositions are universal but only that they are sufficiently widespread to be predictable.

Turning to the second point, does knowing the premises of the your-goal-is-my-goal inference sometimes put one in a position to know the conclusion? Of course the inference is not deductive and will only work when certain background conditions are met. These background conditions include the other having largely true beliefs concerning which goal your actions are or will be directed to. After all, the other agent may be willing to act jointly with you while being entirely mistaken about the goals to which your actions will be directed. Where this happens, the premises of the inference might be true but the conclusion false. (We return to this point in section 8 on page 23.) But there are situations in which it is reasonable to ignore this possibility, as for instance when stereotypes, conventions or simplicity should and do make the goal of your actions obvious to the other agent. Given the right conditions, that others are willing to engage in joint action with you is sometimes sufficient reason to hold that you will end up acting jointly with them even where the goal to which your actions will be directed is already fixed.

In short, then, the two requirements for the your-goal-is-my-goal inference to characterise a route to knowledge are met. In some cases it is possible to know the premises without already knowing the conclusion thanks to natural expressions of willingness to engage in joint action. And knowing the premises sometimes puts one in a position to know the conclusion thanks to the fact that, when things are going well, another's willingness to engage in joint action with you can be based on an accurate assessment of the goals of your actions.

The your-goal-is-my-goal route to knowledge is characterised by an inference. However, exploiting this route to knowledge may not require actually making the inference or knowing the premises. Depending on what knowing requires, it may be sufficient to believe the conclusion because one has reliably detected a situation in which the premises of the inference are true; it

may not be necessary to think of this situation as a situation where the premises are true, nor even to be able to think of it in this way.

In principle, exploiting your-goal-is-my-goal does not require that the interpreter actually be in a position to interact with her target. It is sufficient (and would be necessary but for some special cases) that the target takes the interpreter to be in a position to interact with him. Our concern, however, is with cases that are likely to be important for understanding development or evolution (and ideally both). This mandates a focus on interpreters of limited sophistication who lack both deep insight into others' minds and fully-fledged communicative abilities. Such interpreters are unlikely to be able to contrive or exploit situations in which they only appear to be in a position to interact with their targets. So the explanatorily relevant cases are those in which an interpreter is manifestly in a position to interact with her target.

Our aim in identifying the your-goal-is-my-goal is not to defend a detailed hypothesis about the mechanisms and processes involved in mindreading. Instead our present concerns are limited to a normative question about the evidential basis of mindreading. The your-goal-is-my-goal inference matters not because it describes how interpreters actually assign goals but because it characterises a route to knowledge that is closed to mere observers but open to interacting mindreaders.

6. Avoiding the problem of opaque means

The problem of opaque means was this: failures to identify to which ends actions are means can impair goal ascription (see section 3 on page 10). Showing how your-goal-is-my-goal makes avoiding this problem possible is a way of demonstrating the potential value to mindreaders of interaction.

In our earlier example a novice parent is struggling to lift his heavy twin pram onto a bus when a stranger joins in and they lift the pram together (on page 14). Suppose the stranger starts

tipping the pram in a way that the inexperienced parent fails to recognise as a means, indeed the only means, of getting it onto the bus. Outside the context of joint action this might give the parent sufficient evidence to reject the idea that the goal of the stranger's actions is to get the pram onto this bus. Or suppose the stranger starts by pulling the pram away from the bus in order to better position it for entry, and the novice parent does not realise that this is necessary. Outside the context of joint action, his evidence might on balance support the conclusion that the goal of the stranger's actions is to take the pram off the bus. (Perhaps the stranger is impatient to get onto the bus herself.) But in the context of joint action, your-goal-is-my goal gives the parent additional evidence for supposing that, even though the stranger's actions do not seem to him to be a means to getting the pram onto the bus, this really is the goal of her actions. Of course this additional evidence will not necessarily trump other evidence. But it does provide a possible way around the problem of opaque means by providing evidence for goal ascriptions that is independent of a mindreader's understanding of which ends actions are means to.

We saw earlier that the problem of opaque means may impair goal ascription where actions involve novel uses for tools. How could your-goal-is-my-goal mitigate the problem in such cases? Imagine we are interacting with a young child, Ayesha, and want her to understand how a new tool is used. It is difficult to convey this to her directly. So we first get her interested in achieving an outcome that would require the new tool, knowing that she will perform actions directed to achieving this outcome. We then signal to Ayesha that we are willing to act jointly with her. Now she is in a position to know what the goal of our action will be when we deploy the tool. She is able to identify this goal despite being unable to recognize it as an end to which our tool-using action is a means. She is able to identify this goal because she knows that this is her goal and that we were willing to engage in joint action with her. This is one illustration of how interacting mindreaders have at their disposal ways of identify-

ing the goals of actions involving novel uses of tools which are unavailable to mindreaders who can only observe.

As this example indicates, exploiting your-goal-is-my-goal can shift the burden of identifying goals from a mindreader to her target. In the example Ayesha is the focal mindreader and we are her target; but her success in identifying the goal of our actions depends on this, that our willingness to act jointly with her is based on *our* knowledge of the goals of *her* actions. In purely observational mindreading, the target's beliefs about the goals of the mindreader's actions are not normally relevant (except, of course, when the mindreader is ascribing such beliefs). But interacting mindreaders who rely on your-goal-is-my-goal thereby rely on their targets' having correctly identified the goals of their actions. Of course this is sometimes a reason not to rely on your-goal-is-my-goal. But where the target has better understanding of relevant means-ends relations, such as actions involving novel tools, the your-goal-is-my-goal route to knowledge of other's goals may sometimes be the only option.

The distant promise of all this is that understanding how interaction widens the evidential basis for mindreading may eventually enable us to explain the origins (in evolution or development, and ideally both) of abilities to learn novel and opaque uses for tools from other agents without assuming that rich communicative skills or sophisticated forms of mindreading must already be present.

7. Communicative gestures

When introducing the problem of opaque means (in section 3 on page 10) we saw that it could affect communicative actions. To illustrate this suggestion we drew on an experiment by Hare & Tomasello (2004) in which chimpanzees had to find a reward and were helped by being shown either a failed reach or a helpful point to the target location. Strikingly, for chimpanzees the helpful point is no help at all—even though it superficially re-

sembles the failed reach, which did help. Taking this paradigm as a case study, we want to suggest that your-goal-is-my-goal might enable us to understand how abilities to engage in joint action could be part of what enables mindreaders to make the transition from a simple understanding of goals to an early understanding communicative actions.¹⁹

Let us imagine ourselves as the chimpanzee for a moment. We witness the pointing action. With our eyes we follow the point to a container (see Moll & Tomasello 2007, p. 6). So we do associate the pointing action with its target. But we are no more likely to choose this container than the other in seeking the reward. So we probably do not think of the pointing action as having any goal which would clue us in to the relevance of the container it indicates. (In principle we might perfectly understand the pointing action while failing to react to it in any systematic way because we are uncertain about the agent's integrity; but let us discount this possibility for the sake of illustration.) Now suppose that, before pointing, the agent had used engaging facial gestures to signal willingness to engage in joint action with us; and that we were able to think of retrieving the food as a possible distributive goal²⁰ of our actions; and that we had exploited the my-goal-is-your-goal inference. Then we would believe, perhaps mistakenly, that a goal of the pointing action was to retrieve the food. In which case the pointing action would have been no less helpful in enabling us to succeed than the failed reach—which, as you may recall, was very helpful. So the your-goal-is-my-goal inference can enable interpreters to misunderstand pointing actions as something like failed reaches rather than as communicative gestures.

¹⁹ Please note that, although our discussion borrows an experimental paradigm our aim is not to argue for empirical hypotheses about chimpanzee social cognition. Our aim is only to argue for the theoretical significance of interaction for mindreading by showing that your-goal-is-my-goal could *in principle* enable individuals to make the transition from a simple understanding of goals to an early understanding of communicative actions. Of course it would strengthen our argument if we could provide evidence to show that this actually happens. But for now we are concerned with more narrowly conceptual issues.

²⁰ On *distributive goal* see section 4 on page 13.

This means that, even without any understanding of communication, they can respond appropriately to helpful pointing actions in the context of joint action.

It is natural to suppose that the difficulty chimpanzees have in Hare and Tomasello's experiments with responding appropriately to helpful pointing but not to failed reaching is due to a failure to understand communicative intention.²¹ What we are suggesting is that participants must also have been unable or unwilling to exploit the your-goal-is-my-goal inference.

Consider a related experiment by Leekam, Solomon & Teoh (2010). Again participants had to retrieve a reward from one of several closed containers, but this time they were two- and three-year-old children. In one condition participants were shown an adult holding up a replica of the target container. Leekam and colleagues found that when this action was accompanied by an engaging facial expression, three-year-old children were significantly better at identifying the correct container compared to when the action was accompanied by a neutral facial expression (p. 116). Why did the engaging facial expression enhance performance? The authors consider the idea that engaging facial gestures somehow help children to understand communicative intentions.²² An alternative possibility is that children succeeded without understanding the replica as a sign at all. Instead they may have associated the replica with the container it resembled (which by itself is not enough to motivate selecting this container, of course), regarded the engaging facial gestures as expressing willingness to engage in joint action, and

²¹ See footnote 15 on page 12. Relatedly, in their discussion of these findings Moll and Tomasello suggest that 'to understand pointing, the subject needs to understand more than the individual goal-directed behaviour. She needs to understand that by pointing towards a location, the other attempts to communicate to her where a desired object is located; that the other tries to inform her about something that is relevant for her' (Moll & Tomasello 2007, p. 6). Assuming this is right, our suggestion is that individuals could reliably respond appropriately to pointing actions in the context of joint action without understanding pointing.

²² Leekam et al. (2010, p. 118): 'the adult's social cues conveyed her communicative intent, which in turn encouraged the child to 'see through the sign' ... helping them to take a dual stance to it.'

exploited your-goal-is-my-goal to infer that a goal of the action of holding up the replica was to find the reward. In this way they might have understood (or misunderstood) the action of holding up the replica as like a failed reach in being an attempt to retrieve the reward.

So far we have illustrated how your-goal-is-my-goal enables responding appropriately to communicative gestures with two examples, pointing and holding up a replica. The pattern of reasoning generalises to a wider range of communicative gestures including single-word utterances. The basic requirement is this: in a particular context, the interpreter must associate a communicative gesture with its referent. For instance, she must associate the pointing gesture with the object indicated; or, if (say) she is looking for an object she must associate an utterance of ‘cupboard’ with the nearby cupboard. As we saw, outside the context of joint action, merely associating a gesture with its referent falls short of being able to respond appropriately. After all, the goals of the gesture may well be unrelated to the goals of the interpreter’s actions. But if an interpreter supposes that her target is willing to engage in joint action with her, then she may infer that the goal of her target’s action is her goal and so be motivated to treat the thing associated with a communicative gestures as relevant to the goal of her own actions. This will reliably (but not always) enable her to respond appropriately to the communicative gesture even without understanding it as a communicative gesture. And once she has experienced how that communicative gesture works as a tool for guiding others’ actions in the context of joint action, she may be in a position to realise, further, that the same tool can be used in other contexts.

This, in barest outline, is how abilities to engage in joint action mean that a mindreader with an ability to ascribe simple goals only and no understanding of communicative intent might nevertheless reliably respond appropriately to some communicative gestures, and so come be in a position to understand how such gestures can be used to guide others’ actions.²³ Of

²³ Contrast Csibra’s claim that, early in human development, goal ascription (‘teleological

course we have only argued that this transition is theoretically possible; we have not attempted to defend any hypothesis about anything's evolution or development. Our point is just to illustrate one of several ways in which interaction may matter for mindreading. Widening the evidential basis for goal ascription to include evidence available only to interpreters capable of joint action with their targets makes possible novel hypotheses about the emergence, in evolution or development (and perhaps even both), of communicative gestures.

8. The problem of false belief

So far we have been arguing for the value of interaction to interpreters on the grounds that interacting interpreters, unlike mere observers, have a route to knowledge of the goals of others' actions which avoids the problem of opaque means. There is another reason for supposing that interaction matters for interpretation. To introduce this reason we must first describe another problem affecting interpreters, the problem of false belief.

The problem of opaque means occurs when interpreters must rely entirely on observation and cannot identify to which ends actions are means. A yet more familiar problem affecting goal ascription arises from the interdependence of beliefs and goals. To illustrate, imagine sitting at a table. On the table are two closed opaque boxes. One box contains an owl, the other a cat. If the goal of your action is to retrieve the cat, and you believe that the cat is in the north box, then (unless things are going very badly) you will reach for the north box. But of course if you had believed instead that the cat was in the south box, then, in acting on the same goal, you would have reached for

understanding' in his terms) and identifying the referents of communicative gestures ('referential understanding') 'rely on different kinds of action understanding' and are initially two distinct 'action interpretation systems' (Csibra 2003, p. 456). We have not shown that this hypothesis wrong. But we have shown that there is another possibility: the referential stance may emerge from the teleological stance together with abilities to engage in simple forms of joint action.

the south box. Now consider Ayesha who is observing your actions. Suppose Ayesha has sufficient reason to believe, falsely, that you know the cat is in the south box. Then she may be justified in supposing, incorrectly, that the goal of your action, in reaching for the north box, is to retrieve the owl. As this illustrates, differences in belief between observers and protagonists can impair goal ascription when the interpreter is unaware of those differences. Call this the problem of false belief.

The your-goal-is-my-goal route to knowledge sometimes enables interpreters to avoid the problem of false belief. To illustrate consider a counterfactual alternative to the above example. Ayesha dislikes the owl and is concerned with retrieving the cat. As you reach for the north box, your facial gestures signal willingness to engage in joint action with Ayesha. She then concludes, correctly, that your goal is her goal, to retrieve the cat. So despite the difference in belief, the possibility of interaction means that Ayesha can knowledgeably identify the goal of your action.

Exploiting your-goal-is-my-goal does not make it possible to avoid the problem of false belief entirely, it only shifts the problem. To illustrate, in the above example Ayesha's ability to correctly identify the goal of your action depends on your correctly anticipating the goals of her actions—on your knowing that she is concerned with retrieving the cat. If you incorrectly anticipated that her actions would be directed to retrieving the owl, Ayesha would have been mistaken in taking your actions to be directed to retrieving the cat. As this indicates, exploiting your-goal-is-my-goal can shift both *which* differences in belief have the potential to impair goal ascription and also *who* needs to be aware of those differences.

In short, then, abilities to engage in joint action provide an interpreter with a route to knowledge of the goals of other agents' actions which does not depend on her knowledge of what her target believes. This is not because abilities to engage in joint action provide a way to avoid the problem of false beliefs altogether. Rather they shift the burden of resolving the problem of

false belief from an interpreter to her target. This is potentially valuable for interpreters who have limited insight into their targets' beliefs, or who lack abilities to track differences in belief altogether.

On a purely observational model of interpretation, it seems inevitable that an interpreter who is unable to track others' beliefs will have to proceed as if there were no differences in beliefs. As several philosophers' arguments suggest, it is plausible that the interdependence of beliefs and goals means that an interpreter will always be able to assign goals to others' actions in a way that is consistent with their beliefs not differing from her own (*refs: Davidson; Bennett 1976, p. 49). If so, on a purely observational model of interpretation there is no straightforward way in which the need to track differences in belief will become apparent to an interpreter. Things are different if we extend our model of interpretation to take into account the possibility of interaction. We can then see how an interpreter who is unable to track others' beliefs will encounter anomalies. For some differences in belief will mean that ordinary, purely observational routes to knowledge will result in ascribing one goal whereas exploiting your-goal-is-my-goal would result in ascribing a different goal. That is, the evidence available to an interpreter may inexplicably support two incompatible ascriptions. In this way, differences in belief have the potential to cause puzzling anomalies even before the interpreter is able to track such differences. This raises the possibility that abilities to engage in joint action may play a role in explaining how awareness of belief emerges.

9. Conclusion

Our aim was to show that interaction can facilitate mindreading in this sense: some routes to knowledge are closed to mindreaders who rely exclusively on observation but open to interacting mindreaders. In pursuing this aim we focused on interactions which are joint actions. Our suggestion was this. Where an in-

interpreter recognizes that her target is willing to engage in joint action and is unwilling to change which goals her own actions will be directed to, she may be in a position to know that the goals of her target's actions will be her goals. This in outline is the 'your-goal-is-my-goal' route to knowledge.

To show that this route to knowledge is potentially valuable, we argued that it enables interpreters to overcome two problems, the problem of opaque means and the problem of false belief. These problems may rarely arise for human adults thanks to sophisticated linguistic communication and extensive knowledge of how things can be achieved. But interest in the evolution or development of mindreading motivates focusing on interpreters with absent or fledgling communicative skills, limited insight into others' minds and narrow knowledge of how things work. For such interpreters the problems of false belief and opaque means may easily arise, particularly in cases involving novel tools and communicative gestures. Interpreters could overcome the two problems by exploiting the your-goal-is-my-goal route to knowledge. It follows that expertise with tools and communicative gestures does not presuppose knowledge of others' intentions and beliefs. Such expertise, far from presupposing sophisticated forms of mindreading, might instead play a role in explaining their emergence in evolution or development (or both).

How might this work? ***sketch the story*** Clearly this is a wild conjecture, and not one that we have given any reason for accepting. Our point in mentioning it is merely to illustrate how better understanding the role of interaction in goal ascription and mindreading generally may eventually lead to discoveries on how sophisticated forms of cognition emerge from conceptually and cognitively undemanding forms of interaction. If the culture of tool use, the simpler forms of communicative gesture or the sharing of knowledge and other mental states originates in abilities to interact, then we need to know how interaction could lead to the emergence of these things. Our suggestion has been that understanding how interacting mindreaders could

know things about their minds which mere observers might not be in a position to know will provide some of the details.
